This document describes the procedure to be used by WSDOT engineers for conducting a pavement type selection. There are three primary areas that need to be addressed; pavement design analysis, life cycle cost analysis, and engineering analysis. Each of these areas can have a significant impact on the selected pavement type and will be further described in this protocol. The overall process is shown in Figure 1.

The pavement type selection protocol is applicable to all new alignment, ramps, collector-distributors, acceleration-deceleration lanes, and existing pavement reconstruction on interstate, principal arterials, and any other roadway that may benefit from this analysis. Pavement type selection is not necessary for chip seal roadways. For mainline widening, if the selected pavement type is the same pavement type as the existing, then a pavement type selection is not required. When comparing life cycle costs of the different alternatives, the comparison must be based on the total costs, which include initial construction, maintenance, rehabilitation, and user costs.

## APPLICATION OF PAVEMENT TYPE SELECTION

The following is a list of considerations for new construction or reconstruction of mainline, ramps, collector-distributors, acceleration-deceleration lanes, and intersections.

- **Mainline lane reconstruction.** A pavement type selection must be completed on all mainline pavements that are more than ½ lane mile in length or more than \$0.5M. For roadway segments shorter in length or lower in cost, the HQ Materials Laboratory should be contacted for further direction on the need to conduct a pavement type selection.
- **Ramps.** For ramps with mature (lane configuration or right of way limits the expansion of the roadway footprint) geometrics, high traffic and high truck percentages both portland cement concrete (PCC) and hot mix asphalt (HMA) pavement should be considered.
- **Collector-Distributors.** Collector-distributors should be designed similarly as ramps above.
- **Acceleration-Deceleration Lanes.** Treat the same as collector-distributors.
- **Intersections.** Most intersections will not require an analysis separate from the rest of the highway. However, intersections with chronic, relatively short term, rutting should be examined in detail to determine the nature and cause of the rutting and to carefully consider alternate pavement types. The State Materials Laboratory, Pavements Division, should be contacted for further guidance and direction on options for resolving chronic intersections rutting issues.

**Figure 1. Pavement Type Selection Flow chart**

## **STEP 1: PAVEMENT DESIGN ANALYSIS**

The pavement design should be performed first, since the results may preclude the need to continue with the remainder of the pavement type selection protocol process (life cycle cost analysis and engineering analysis).

The pavement design analysis should include the review and analysis of the following: subgrade competency, traffic analysis, materials, climate/drainage, environment, construction considerations, and any other pavement design factors.

### **SUBGRADE COMPETENCY**

This is the only “go/no go” decision to be made under the Pavement Design Analysis. HMA tends to perform better in situations where long-term settlement is expected, due to simplified patching and overlay opportunities compared to PCC pavement. In such cases, the pavement design analysis might preclude the need to continue with a life cycle cost analysis and the engineering analysis if subgrade conditions will not allow the use of PCC pavement. If the engineering evaluation of the subgrade concludes that PCC pavement cannot be placed or will not perform successfully, then the pavement type selection is complete and HMA is the selected pavement type. If the engineering evaluation of the subgrade concludes that either pavement type could be used successfully, proceed with the remainder of the Pavement Type Selection Protocol.

### **CLASSIFICATION FOR PAVEMENT DESIGN**

Pavements can be divided into different traffic classes depending on extremely light to extremely heavy traffic. Flexible and rigid pavements can be designed to accommodate these wide traffic ranges. For each of the pavement classes, traffic can be quantified by the number of standard axles/lane (or load spectra) or by traffic volume (e.g., average daily traffic (ADT), annual average daily traffic (AADT), annual average daily truck traffic (AADTT), or percent trucks). Based on the traffic volume and traffic growth rate, the design traffic loading can be estimated over the structural design period or the analysis period. The design traffic loading determines the pavement thickness needed to support the traffic loading over the structural design period.

Correctly estimating design traffic is crucial to selecting an appropriate pavement. To calculate the total design traffic per lane that a pavement will carry over its structural design life, it is necessary to estimate present traffic loading. To estimate future traffic loadings, traffic growth rates should be used. Depending on the roadway segment’s importance, conducting a sensitivity analysis to compare growth rates and the impact of the growth rate on pavement thickness may be worthwhile.

### **MATERIALS**

Selecting materials for a road pavement design is determined by the availability of suitable materials, environmental considerations, construction methods, economics, and previous performance. To select the materials that best suit the conditions, these factors must be evaluated during the design to ensure a whole-life cycle strategy.

#### **Availability and Performance**

Most road construction materials have been classified and specifications prepared for each of the material classes. Every road pavement, independent of its type and applied materials, is subjected to certain traffic loads and environmental factors. These factors create various deterioration modes under in-service conditions. Deterioration modes and the pavement’s susceptibility to various deteriorating factors depend on the type of pavement and materials applied. Table 1 shows the pavement deterioration modes for HMA and PCC pavements.

**Table 1. Pavement Deterioration Modes**

<b>HMA Pavements</b>	<b>PCC Pavements</b>
<ul style="list-style-type: none"> <li>▪ Surface deterioration <ul style="list-style-type: none"> <li>– Decrease in friction</li> <li>– Rutting</li> <li>– Surface cracking</li> <li>– Ravelling (stripping)</li> <li>– Roughness</li> <li>– Studded tire wear</li> </ul> </li> <li>▪ Structural deterioration <ul style="list-style-type: none"> <li>– Base and subgrade rutting</li> <li>– Fatigue cracking</li> <li>– Reflective cracking</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>▪ Surface deterioration <ul style="list-style-type: none"> <li>– Decrease in friction</li> <li>– Surface cracking</li> <li>– Curling and warping</li> <li>– Joint ravelling</li> <li>– Roughness</li> <li>– Studded tire wear</li> </ul> </li> <li>▪ Structural deterioration <ul style="list-style-type: none"> <li>– Cracking</li> <li>– Pumping</li> <li>– Faulting</li> </ul> </li> </ul>

Pavement surface defects may only require surface course maintenance or rehabilitation. Structural deterioration is a defect of the whole pavement structure and treating it may require more extensive pavement rehabilitation. Knowing the difference between these two types of deterioration is important to maintaining and properly understanding pavement durability (or pavement life).

Past performance with a particular material should be considered in tandem with applicable traffic and environmental factors. The performance of similar pavements or materials under similar circumstances should also be considered. Information from preexisting designs, material tests, and pavement management data can help characterize a specific material's suitability for pavement applications.

WSDOT's experience has been that all pavement types are affected by studded tire wear (see Figures 2 and 3). The abrasion on pavement surfaces caused by studded tires, wears down the pavement surface at a much greater rate than any other pavement/tire interaction. Surface deterioration has occurred in as little as 4 to 6 years on HMA and 10 to 15 years on PCC pavements. For the pavement type selection process, this implies that future rehabilitation timing may be reduced for each pavement type due to the damaging effect of studded tires and should be considered in the analysis until such a time that studded tire use is prohibited.

**Figure 2. Studded Tire Wear on PCC**

**Figure 3. Studded Tire Wear on HMA**

## Recycling

To enhance sustainable development, consider using recycled materials in roadway construction. Future rehabilitation or maintenance treatments, if applicable, should incorporate recycled materials whenever possible.

## CLIMATE/DRAINAGE

Both surface runoff and subsurface water control must be considered. Effective drainage design prevents the pavement structure from becoming saturated. Effective drainage is essential for proper pavement performance and is assumed in the structural design procedure.

## PAVEMENT DESIGN

Pavement design shall be conducted in accordance with the AASHTO Guide for Design of Pavement Structures – 1993 and the WSDOT Pavement Guide – Volume 1. All pavement designs, rehabilitation strategies, and rehabilitation timing must be submitted, for approval, to the Pavement Design Engineer at the State Materials Laboratory in Tumwater, Washington.

Input values to be used in the AASHTO Guide for Design of Pavement Structures – 1993 are shown in Table 2. Additional information can be obtained from the WSDOT Pavement Guide.

**Table 2. WSDOT Inputs for AASHTO Pavement Design**

Input Parameter	HMA	PCC
$\Delta PSI$	1.5	1.5
$a_{HMA}$	0.44	N/A
$a_{CS}/k$	0.13	200
$a_{HMA \text{ base}}/k$	0.44	400
$C_d$	N/A	1.0
$E_c$	N/A	4,000,000 psi
J (dowels)	N/A	2.7
J (no dowels)	N/A	3.4
$k_{CSBC}$	N/A	200 pci
$k_{HMA \text{ base}}$	N/A	400 pci
M	1.0	N/A
$M_R$ (average soil)	10,000 psi	N/A
$M_R$ (good soil)	20,000 psi	N/A
$M_R$ (poor soil)	5,000 psi	N/A
$S_c'$	N/A	650 psi
$S_o$	0.50	0.40

## Additional PCC Issues

WSDOT has demonstrated that the PCC pavements constructed in the late 1950's to early 1960's are able to obtain a 50-year or more pavement life as long as joint faulting can be overcome. The ability to provide adequate joint design to minimize joint faulting is addressed by requiring the use of non-erodable bases and dowel bars (1-½ inch diameter by 18 inch length) at every transverse joint. The use of epoxy-coated dowel bars, both locally and nationally, does not necessarily ensure that a 50-year performance life will be obtained. Several states have observed that the corrosion of epoxy coated dowel bars occurs within 15 to 20 years. Minnesota Department of Transportation has conducted a study of in-service concrete pavements that were constructed with epoxy-coated steel dowel bars at transverse joints and has determined that significant corrosion has occurred in the dowel bars. The result of this study has indicated that

the corrosion of epoxy coated dowel bars results in a pavement life of less than 20 years (dowel bar corrosion leads to joint deterioration which requires either complete replacement of the concrete pavement or a dowel bar retrofit). California Department of Transportation is currently conducting a study on the corrosion rates of a variety of different dowel bars (epoxy coated, solid stainless steel and stainless steel clad) and is finding that the epoxy-coated bars are failing the corrosion testing, while the stainless steel bars (clad and solid) are experiencing no corrosion. Therefore, WSDOT currently requires the use of stainless steel clad dowel bars on all newly constructed concrete pavements (see Standard Plan A-1). The anticipated life of a PCC pavement shall be on the order of 50 years. Rehabilitation of these PCC pavements will potentially require diamond grinding at the 20 to 30 year range to address studded tire wear.

### **Additional HMA Issues**

For heavily trafficked roadways (primarily the interstate and principal arterials), the pavement thickness should be designed to such a depth that future roadway reconstruction is not necessary. The pavement thickness should be designed such that 50 years of traffic will not generate significant bottom up (fatigue) cracking. Future mill and fill or HMA overlay will be required to address surface distress (rutting or top down cracking) and aging of the HMA surface.

### **Effect of Studded Tire Wear**

WSDOT is currently in the process of investigating a number of mitigation techniques for the wear that results on PCC pavements due to studded tires. These include increasing the PCC flexural strength and utilization of a combined aggregate gradation. At this time, both of these studies are still in progress and conclusions are yet to be drawn. Therefore, to combat the damaging effects of studded tires, it is recommended that the PCC thickness be increased by one inch to accommodate future diamond grinding(s). This damage is also a concern for HMA pavements. WSDOT has constructed a number of stone matrix asphalt (SMA) pavements, but have had a number of construction related difficulties, such that the ability to determine the impact that an SMA will have on reducing studded tire damage has yet to be determined. In the life cycle cost analysis, the accelerated wear on HMA pavements will be incorporated through a shorter performance period on future overlays (as supported by Pavement Management data).

## **CONSTRUCTION CONSIDERATIONS**

Pavement construction issues are an important component of the selection of pavement type. These issues can include:

- Pavement thickness constraints. Consider the impact of utilities below the pavement and overhead clearances may have on limiting the layer thickness and type, and/or limit future overlay thickness.
- Effects on detours, bypasses, and alternate routes. Consider the geometric and structural capacity of detours, bypasses and alternate routes to accommodate rerouted traffic.
- Effects of underground pipes and services on performance. Determine the impact of existing utilities and future utility upgrades on initial and future rehabilitation treatments.
- Anticipated future improvements and upgrades. Consider if the pavement type restricts or minimizes the ability to efficiently and cost effectively upgrade and/or improve the roadway width, geometry, structural support, etc.
- Impact on maintenance operations, including winter maintenance. Will the selected pavement type have impacts due to freeze-thaw (surface and full-depth) or snow and ice removal?
- Grades, curvature, and unique loadings (slow-moving vehicles and starting and stopping). How will steep grades, curvature and unique loadings impact pavement performance? Slow moving vehicles will generate increased strain levels in the HMA pavement structure and these strains can significantly impact pavement performance (i.e. rutting and cracking).
- A schedule analysis may need to be conducted to determine critical construction features (haul truck access, traffic control constraints – road closures, etc) and their impact on the project. This should also include staging analysis for multiple projects within the project corridor (to ensure

that alternate routes are free of traffic delay due to construction activities). The Construction Analysis for Pavement Rehabilitation Strategies CA4PRS<sup>1</sup> software is useful in determining construction impacts and duration.

#### **OTHER FACTORS**

Evaluate other factors that are unique to the project or corridor.

---

<sup>1</sup> The CA4PRS software can be downloaded at <http://wwwi.wsdot.wa.gov/maintops/mats/apps/CA4PRS.htm>.

## STEP 2: LIFE CYCLE COST ANALYSIS

Life cycle cost analysis provides a useful tool to assist in the pavement type selection. Only differential factors should be considered. The alternative resulting in the lowest net present value or annualized cost over a given analysis period is considered the most cost efficient.

Life cycle costs refer to all costs that are involved with the construction, maintenance, rehabilitation and associated user impacts of a pavement over a given analysis period. Life cycle cost analysis is an economic comparison of all feasible construction or rehabilitation alternatives, evaluated over the same analysis period. "A feasible alternative is one that fits with the required constraints (e.g., geometric, construction time, traffic flow conditions, clearances, right-of-way, maximum funds available, etc.)" [1]. At a minimum, one HMA and one PCC alternative should be evaluated. The total cost (initial construction, maintenance, rehabilitation, and user costs) of each design alternative can be compared based on the present value or equivalent uniform annual cost.

The life cycle cost analysis should be conducted using the FHWA life cycle cost analysis software, which is available through the State Materials Laboratory – Pavements Division<sup>2</sup>.

The Federal Highway Administration's policy<sup>3</sup> on life cycle cost analysis "is that it is a decision support tool, and the results of the life cycle cost analysis are not decisions in and of themselves. The logical analytical evaluation framework that life cycle cost analyses fosters is as important as the life cycle cost analysis results themselves." [4].

Net present value is the economic efficiency indicator of choice [4]. The annualized method is appropriate, but should be derived from the net present value. Computation of benefit/cost ratios is generally not recommended because of the difficulty in sorting out costs and benefits for use in the benefit/cost ratios [4].

Future costs should be estimated in constant dollars and discounted to the present using a discount rate. The use of constant dollars and discount rates eliminates the need to include an inflation factor for future costs.

### NET PRESENT VALUE

The present value method is an economic method that involves the conversion of all of the present and future expenses to a base of today's costs [2]. The totals of the present value costs are then compared one with another. The general form of the present value equation is as follows:

$$NPV = F \frac{1}{(1+i)^n}$$

where,

NPV = Net Present Value  
F = Future sum of money at the end of n years  
n = Number of years  
i = Discount rate

---

<sup>2</sup> <http://www.wsdot.wa.gov/MaintOps/mats/apps/LCCA.htm>

<sup>3</sup> Federal Highway Administration, Final Policy Statement on LCCA published in the September 18, 1996, *Federal Register*.

## ANNUALIZED METHOD

The annualized method is an economic procedure that requires converting all of the present and future expenditures to a uniform annual cost [2]. This method reduces each alternative to a common base of a uniform annual cost. The costs are equated into uniform annual costs through the use of an appropriate discount rate [3]. Recurring costs, such as annual maintenance, are already expressed as annual costs. A given future expenditure, such as a pavement overlay, must first be converted to its present value before calculating its annualized cost. The general form of the Annualized cost equation is as follows:

$$A = PV \frac{i(1+i)^n}{(1+i)^n - 1}$$

where,

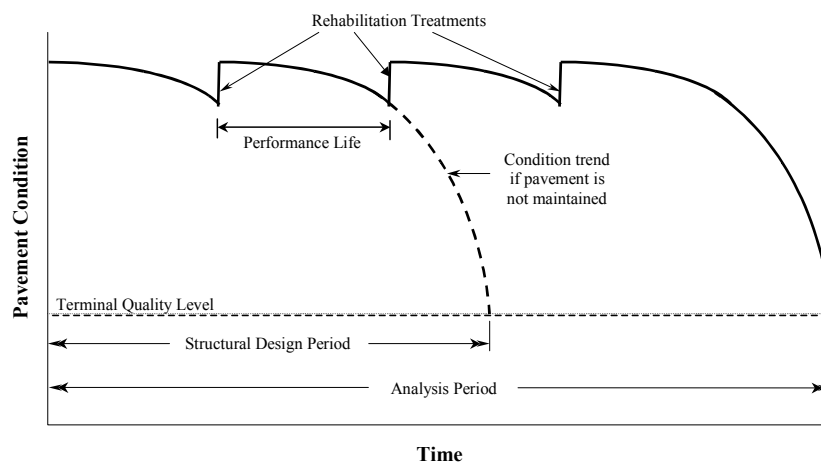

A = Annual cost  
PV = Present Value  
n = Number of years  
i = Discount rate

## ECONOMIC ANALYSIS

The costs to be included in the analysis are those incurred to plan, work on and maintain the pavement during its useful life. All costs that can be attributed to the alternative and that differ from one alternative to another must be taken into account. These include costs to the highway agencies and user costs.

### Performance Period

As a pavement ages, its condition gradually deteriorates to the point where some type of rehabilitation treatment is necessary. The timing between rehabilitation treatments is defined as the performance life. An example of this is illustrated in Figure 4. Performance life for the initial pavement design and subsequent rehabilitation activities has a major impact on life cycle cost analysis results [4].

**Figure 4. Example of Pavement Performance Life**

When available, the performance life of the various rehabilitation alternatives should be determined based on past performance history. In these cases, the Washington State Pavement Management System provides history on past pavement performance lives. In instances where

the anticipated performance life is not well established (i.e., due to improved engineering and technologies), selection of the performance life should be coordinated and concurred upon with the State Materials Laboratory – Pavements Division.

### **Initial Construction Costs**

Unit costs vary according to location, the availability of materials, the scope of the project, and the standards to be complied with. They can be estimated based on previous experiences, generally by averaging the bids submitted for recent projects of similar scope. Typical item costs can be located in bid item tabulations. The bid item costs may need to be adjusted according to local availability and work constraints. Mobilization, engineering and contingencies, and preliminary engineering can be excluded (sales tax should be included) for the initial construction cost estimate, since these costs are similar for HMA and PCC.

### **Maintenance and Rehabilitation Costs**

The type and frequency of future maintenance and rehabilitation operations vary according to the pavement type being considered. Knowing how a particular pavement type performed in the past is a valuable guide in predicting future performance [5]. The Washington State Pavement Management System should be reviewed for past performance of rehabilitation and maintenance schedules. Costs must always be determined as realistically and accurately as possible based on local context and specific project features.

When calculating the total construction cost, include the cost of pavement resurfacing or PCC rehabilitation, milling or diamond grinding, shoulders, pavement repair, drainage and guardrail adjustments, maintenance and protection of traffic, etc. Mobilization (5%), engineering and contingencies (15%), preliminary engineering (10%), and sales tax should be included in all rehabilitation costs.

Construction duration should reflect the actual construction time that is required for each pavement type. Construction durations should consider improvements, proposals or innovative contracting procedures in construction processes.

If a difference exists in routine maintenance costs between the various alternatives, these costs should be included in the life cycle cost analysis.

Table 3 contains a probable scenario corresponding to average traffic and climate conditions, assuming that state-of-the-art practices have been followed during construction and that maintenance and rehabilitation projects are carried out efficiently and on schedule.

**Table 3. Rehabilitation Scenario for HMA and PCC Pavements (2004 dollars)**

<b>Year</b>	<b>HMA Pavement</b>	<b>PCC Pavement</b>
0	Construction or reconstruction	Construction or reconstruction
15	0.15' mill and HMA overlay	
20		Diamond grinding
30	0.15' HMA overlay	
40		Diamond grinding
45	0.15' mill and HMA overlay	
50	Salvage value (if applicable)	Salvage value (if applicable)

### **Salvage Value**

Salvage value is the asset value at the end of the analysis period. The difference between the salvage values of the various alternatives for a project can be small, because discounting can

considerably reduce this value, but the size of this reduction is influenced by the actual discount rate chosen. As for the value assigned to the pavement materials, or terminal value, predicting the proportion of recovery or recycling of these materials on-site at the end of the analysis period is uncertain.

If an alternative has reached its full life cycle at the end of the analysis period, it is generally considered to have no remaining salvage value. If it has not completed a life cycle, it is given a salvage value, which is usually determined by multiplying the last construction or rehabilitation cost, by the ratio of the remaining expected life cycle to the total expected life.

$$\text{Salvage Value} = \text{CC} \times \frac{\text{ERL}}{\text{TEL}}$$

where,

CC = Last construction or rehabilitation project costs  
 ERL = Expected remaining life of the last construction or rehabilitation project  
 TEL = Total expected life of the last construction or rehabilitation project

### User Costs

It is difficult to determine whether or not one rehabilitation alternative results in a higher vehicle operating cost than another. Therefore, the user costs associated with each of the rehabilitation alternatives shall be determined using only costs associated with user delay. This shall be based on the construction periods and the traffic volumes that are affected by each of the rehabilitation alternatives.

Several studies have been performed that associate cost with the amount of time the user is delayed through a construction project. The method used is not as important as using the same method for each of the alternatives.

The costs associated with user delays are estimated only if the effects on traffic differ among the alternatives being analyzed. For future rehabilitation work, user costs associated with delays can be substantial for heavily traveled roadways, especially when work is frequent.

While there are several different sources for the dollar value of time delay, the recommended mean values and ranges for the value of time (in August 1996 dollars) shown in Table 4, are reasonable.

**Table 4. Recommended Dollar Values per Vehicle Hour of Delay [4] (adjusted to 2004 dollars)<sup>4</sup>**

Vehicle Class	Value Per Vehicle Hour	
	Value	Range
Passenger Vehicles	\$13.96	\$12 to \$16
Single-Unit Trucks	\$22.34	\$20 to \$24
Combination Trucks	\$26.89	\$25 to \$29

### Other Costs

Surfacing types and characteristics influence the noise emitted on tire-to-pavement contact. If construction of a noise attenuation structure is planned, the cost of that structure must be

<sup>4</sup> Calculator for converting costs to current dollars can be accessed at <http://data.bls.gov/cgi-bin/cpicalc.pl>

included in the treatment costs of the alternative being analyzed. The issue of safety can be addressed similarly.

### Discount Rate

"In a life cycle cost analysis, a discount rate is needed to compare costs occurring at different points in time. The discount rate reduces the impact of future costs on the analysis, reflecting the fact that money has a time value" [6]. The discount rate is defined as the difference between the market interest rate and inflation, using constant dollars.

Table 5 shows recent trends in the real treasury interest rates for various analysis periods published in the annual updates to OMB Circular A-94 [7].

**Table 5. Real Treasury Interest Rates [7]**

Year	3-Year	5-Year	7-Year	10-Year	30-Year
1979	2.8	3.4	4.1	4.6	5.4
1980	2.1	2.4	2.9	3.3	3.7
1981	3.6	3.9	4.3	4.4	4.8
1982	6.1	7.1	7.5	7.8	7.9
1983	4.2	4.7	5.0	5.3	5.6
1984	5.0	5.4	5.7	6.1	6.4
1985	5.9	6.5	6.8	7.1	7.4
1986	4.6	5.1	5.6	5.9	6.7
1987	2.8	3.1	3.5	3.8	4.4
1988	3.5	4.2	4.7	5.1	5.6
1989	4.1	4.8	5.3	5.8	6.1
1990	3.2	3.6	3.9	4.2	4.6
1991	3.2	3.5	3.7	3.9	4.2
1992	2.7	3.1	3.3	3.6	3.8
1993	3.1	3.6	3.9	4.3	4.5
1994	2.1	2.3	2.5	2.7	2.8
1995	4.2	4.5	4.6	4.8	4.9
1996	2.6	2.7	2.8	2.8	3.0
1997	3.2	3.3	3.4	3.5	3.6
1998	3.4	3.5	3.5	3.6	3.8
1999	2.6	2.7	2.7	2.7	2.9
2000	3.8	3.9	4.0	4.0	4.2
2001	3.2	3.2	3.2	3.2	3.2
2002	2.1	2.8	3.0	3.1	3.9
2003	1.6	1.9	2.2	2.5	3.2
Average	3.4	3.8	4.1	4.3	4.7
Std Dev	1.1	1.2	1.3	1.4	1.4

For all life cycle cost analysis, WSDOT has selected a discount rate of four percent

### Analysis Period

The analysis period is the time period used for comparing design alternatives. An analysis period may contain several maintenance and rehabilitation activities during the life cycle of the pavement being evaluated [6]. In general, the recommended analysis period coincides with the useful life of the most durable alternative. "In the past, pavements were typically designed and analyzed for a 20 year performance period, since the original Interstate Highway Act in 1956 required that traffic be considered through 1976. It is now recommended that consideration be given to longer

analysis periods, since these may be better suited for the evaluation of alternative long term strategies based on life cycle costs. Consideration should be give to extending the analysis period to include one rehabilitation." [6]. Table 6 contains WSDOT recommended analysis periods.

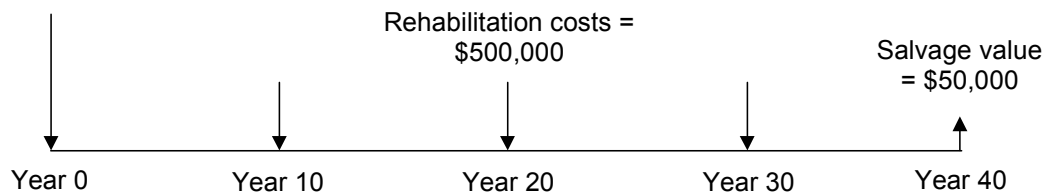

**Table 6. WSDOT Recommended Analysis Periods by Traffic Level**

Traffic Level	Analysis Period (years)
Interstate or Principal Arterial	50
Minor Arterial or Major Collector	20

### Risk Analysis

The deterministic approach to life cycle costs involves the selection of discrete input values for the initial construction costs, routine maintenance and rehabilitation costs, the timing of each of these costs, and the discount rate. These values are then used to calculate a discrete single value for the present value of the specified project. The deterministic approach applies procedures and techniques without regard for the variability of inputs. An example of the deterministic approach is shown in below.

Initial Cost = \$1,000,000

Discount rate = 4 percent

$$\begin{aligned}
 PW &= \$1,000,000 + \frac{\$500,000}{(1.04)^{10}} + \frac{\$500,000}{(1.04)^{20}} + \frac{\$500,000}{(1.04)^{30}} + \frac{\$500,000}{(1.04)^{40}} - \$50,000 \\
 &= \$1,709,720
 \end{aligned}$$

The deterministic approach is a viable method for determining life cycle costs; however, life cycle cost analysis contains several possible sources of uncertainty. In certain cases, the uncertainty factors may be sizeable enough to affect the ranking of the alternatives. To obtain more credible results, a systematic evaluation of risk should always be carried out. The primary disadvantage of the deterministic approach is that it does not account for the input parameter variability.

The concept of risk comes from the uncertainty associated with future events – the inability to know what the future will bring in response to a given action today [4]. Risk analysis is concerned with three basic questions [4]:

1. What can happen?
2. How likely is it to happen?
3. What are the consequences of it happening?

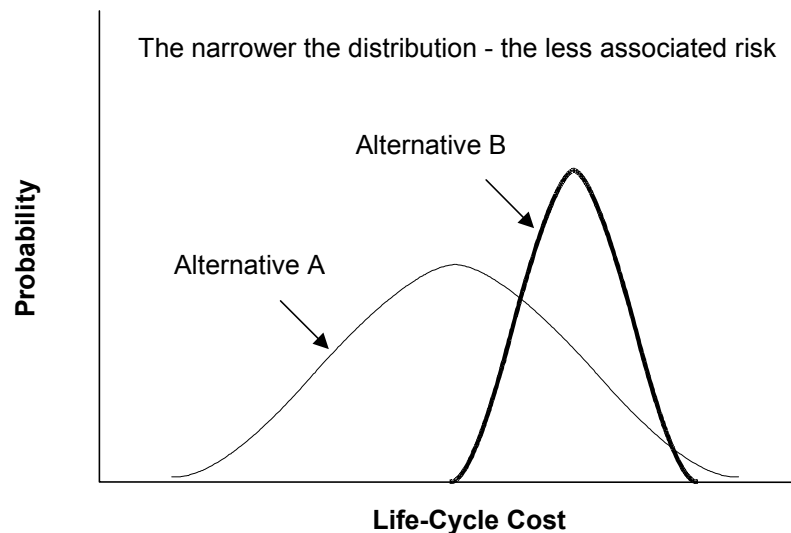

Risk analysis answers these questions by combining probabilistic descriptions of uncertain input parameters with computer simulation to characterize the risk associated with future outcomes [4].

It exposes areas of uncertainty typically hidden in the traditional deterministic approach to life cycle cost analysis, and it allows the decision maker to weigh the probability of an outcome actually occurring [4].

The two most commonly used methods of assessing the risk are probabilistic analysis and sensitivity analysis. The probabilistic approach combines probability descriptions of analysis inputs to generate the entire range of outcomes as well as the likelihood of occurrence. Probabilistic analysis represents uncertainties more realistically than does a sensitivity analysis. Sensitivity analysis assigns the same weighting to all extreme or mean values, whereas probabilistic analysis assigns the lowest probability to extreme values. A probabilistic analysis is advocated, but if this is not possible, a sensitivity analysis at the very least should be carried out.

### *Probabilistic Analysis*

The probabilistic approach takes into account the uncertainty of the variables used as inputs in the life cycle cost analysis. The probability distribution is selected for each input variable, which are then used to generate the entire range of outcomes and the likelihood of occurrences for both the associated costs and the performance life. The procedure often used to apply a probability distribution is a “Monte Carlo Simulation”. The Monte Carlo Simulation is a computerized procedure that takes each input variable, assigns a range of values (using the mean and standard deviation of the input variable), and runs multiple combinations of all inputs and ranges to generate a life cycle cost probability distribution. Using the probabilistic approach allows for the ability of determining the variability or “spread” of the life cycle cost distributions and determining which alternative has the lower associated risk (see Figure 5).

**Figure 5. Probability Distribution**

An example of a probabilistic analysis is included in Appendix 1. WSDOT input values for the probabilistic analysis are contained in Appendix 2.

By performing the Monte Carlo computer simulation, thousands, even tens of thousands of samples are randomly drawn from each input distribution to calculate a separate what-if scenario [4]. Risk analysis results are presented in the form of a probability distribution that describes the range of possible outcomes along with a probability weighting of occurrence [4]. With this information, the decision maker knows not only the full range of possible values, but also the relative probability of any particular outcome actually occurring [4].

### Sensitivity Analysis

Sensitivity analysis is a technique used to determine the influence of major input assumptions, projections, and estimates on life cycle cost analysis results. In a sensitivity analysis, major input values are varied (either within some percentage of the initial value or over a range of values) while all other input values remain constant and the amount of change in results is noted [4].

An example of a sensitivity analysis is shown below.

Two example pavement design strategies with discount rates that vary from two to six percent for a 35-year analysis period.

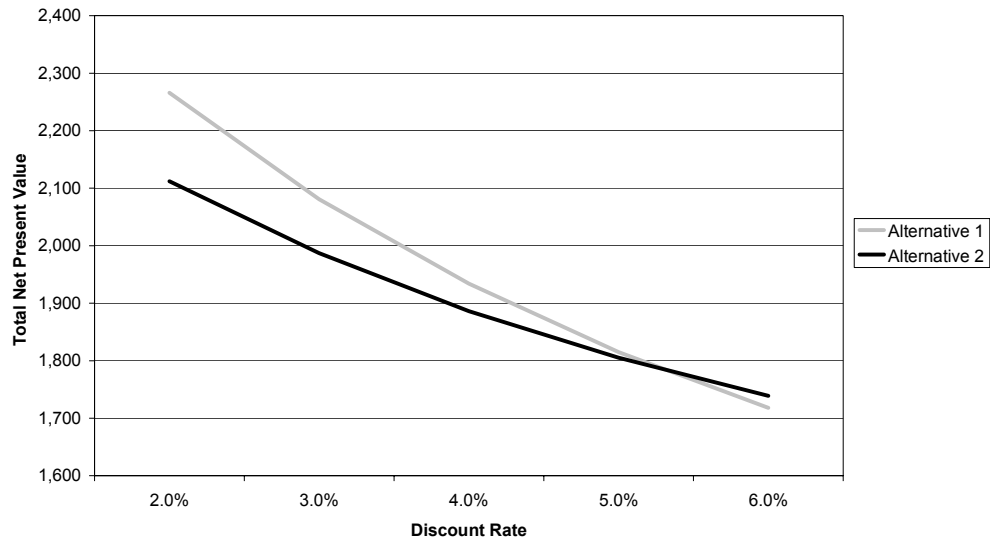

Figure 6 summarizes Tables 7 and 8 and shows the comparison of net present value at the various discount rates. For this example, Alternative 1 is more expensive at discount rates of five percent and lower, while Alternative 2 is more expensive at discount rates six percent and above.

**Table 7. Sensitivity Analysis – Alternative 1 [4]**

Activity	Year	Cost	Net Present Value				
			2.0%	3.0%	4.0%	5.0%	6.0%
Construction	0	975	975	975	975	975	975
User Cost	0	200	200	200	200	200	200
Rehab #1	10	200	164	149	135	123	112
User Cost #1	10	269	220	200	182	165	150
Rehab #2	20	200	135	111	91	75	62
User Cost #2	20	361	243	200	165	136	113
Rehab #3	30	200	110	82	62	46	35
User Cost #3	30	485	268	200	150	112	85
Salvage	35	-100	-50	-36	-25	-18	-13
TOTAL NPV			2,266	2,081	1,934	1,815	1,718

**Table 8. Sensitivity Analysis – Alternative 2 [4]**

Activity	Year	Cost	Net Present Value				
			2.0%	3.0%	4.0%	5.0%	6.0%
Construction	0	1,100	1,100	1,100	1,100	1,100	1,100
User Cost	0	300	300	300	300	300	300
Rehab #1	15	325	241	209	180	156	136
User Cost #1	15	269	200	173	139	129	112
Rehab #2	30	325	179	134	100	75	57
User Cost #2	30	361	199	149	111	84	63
Salvage	35	-217	-108	-77	-55	-39	-28
TOTAL NPV			2,112	1,987	1,886	1,805	1,739

**Figure 6. Sensitivity of Net Present Value to Discount Rate**

A primary drawback of the sensitivity analysis is that the analysis gives equal weight to any input value assumptions, regardless of the likelihood of occurring [4]. In other words, the extreme values (best case and worst case) are given the same likelihood of occurrence as the expected value, which is not realistic [4].

### STEP 3: ENGINEERING ANALYSIS

After completing the pavement design analysis and the life cycle cost analysis, the engineering analysis is conducted when there are two viable alternatives. Finding the HMA and PCC alternatives to be approximately equivalent, the Region must provide their engineering analysis supporting the pavement type selection. The fact that these are not easily quantified does not lessen their importance; in fact these factors may be the overriding reason for making the final pavement type selection. These decision factors should be carefully reviewed and considered, by WSDOT engineers most knowledgeable of the corridor and the surrounding environment.

When offering the engineering analysis for pavement type selection, the Region must not use reasoning or examples that have already been taken into account within the pavement design analysis or the life cycle cost analysis. Examples of reasoning that should **not** be presented in the engineering analysis include:

1. Availability of funds for the more expensive pavement type.
2. Supporting the choice for pavement type based on ESALs or ADT (already accounted for in the life cycle cost analysis).
3. Supporting the choice for pavement type based on user delay (already accounted for in the life cycle cost analysis).

The Region should include the engineering reasons that drive the selection of one pavement type over another, given that their life cycle costs are approximately equivalent. Additional considerations, though not inclusive or exclusive, are found in Appendix 3. Not all factors will come into play on every project, nor will all factors have equal weight or importance on each project. Many of the factors are synergistic, combining or subtracting, depending on the selection and many of the factors are interrelated. Staff intimately familiar with the design goals of the entire project, or entire corridor, should make the engineering analysis evaluations.

## **SUBMITTAL PROCESS**

The pavement type selection, including all applicable subsections (pavement design analysis, cost estimate and life cycle cost analysis, and engineering analysis) shall be submitted electronically to the Pavement Design Engineer at the State Materials Laboratory. The pavement type selection analysis shall be reviewed and distributed to the Pavement Type Selection Committee (see Appendix 5) for approval. The report submittal shall include detailed explanation of the various applicable items, as those outlined above, that supports the selection of the recommended pavement type.

Directional Lanes		Average Capacity	
Normal Operations	Work Zone Operations	Vehicles per Hour	Vehicles per Lane per Hour
3	1	1,170	1,170
2	1	1,340	1,340
5	2	2,740	1,370
4	2	2,960	1,480
3	2	2,980	1,490
4	3	4,560	1,520

## **APPENDIX 2 – PROBABILISTIC ANALYSIS EXAMPLE**

This example is hypothetical. This project involves the removal and replacement of an existing interstate concrete pavement. Roadway configuration is 4 lanes in each direction with 10-foot right shoulders and 4-foot left shoulders. The alternatives evaluated will include:

1. Removal of the existing PCC and replacement with HMA
  - a. Initial construction  
300 mm HMA  
165 mm CSBC  
465 mm Total Depth
  - b. Initial construction thickness design based on 50-year performance with future overlays, 10 year cycle with minimum life of 6 years and maximum of 12 years
  - c. Future Overlays
    - i. 45 mm Overlay in 1<sup>st</sup>, 3<sup>rd</sup>, and 5<sup>th</sup> cycles
    - ii. 45 mm Mill and Fill in 2<sup>nd</sup>, 3<sup>rd</sup>, and 5<sup>th</sup> cycles
2. Removal of the existing PCC and replacement with PCC
  - a. Initial construction  
300 mm HMA  
165 mm CSBC  
465 mm Total Depth
  - b. Initial construction thickness design based on 50-year performance with future rehabilitation in 25<sup>th</sup> year
  - c. Future Rehabilitation
    - i. Diamond grinding to remove studded tire wear and reseal joints every 25 years (minimum of 20 years and maximum of 30 years)
    - ii. 45 mm Mill and Fill in 2<sup>nd</sup>, 3<sup>rd</sup>, and 5<sup>th</sup> cycles (pavement life – minimum of 6 years, most likely 10 years, and maximum 12 years)

## Deterministic Results

Total Cost	Alternative 1: HMA		Alternative 2: PCC	
	Agency Cost (\$1000)	User Cost (\$1000)	Agency Cost (\$1000)	User Cost (\$1000)
Nominal \$	\$30,107.67	\$270,356.78	\$22,317.33	\$261,385.30
Present Value	\$18,891.08	\$240,884.78	\$19,133.72	\$238,485.30
EUAC	\$835.02	\$10,647.55	\$845.75	\$10,541.49
Lowest Present Value Agency Cost			Alternative 1: HMA	
Lowest Present Value User Cost			Alternative 2: PCC	

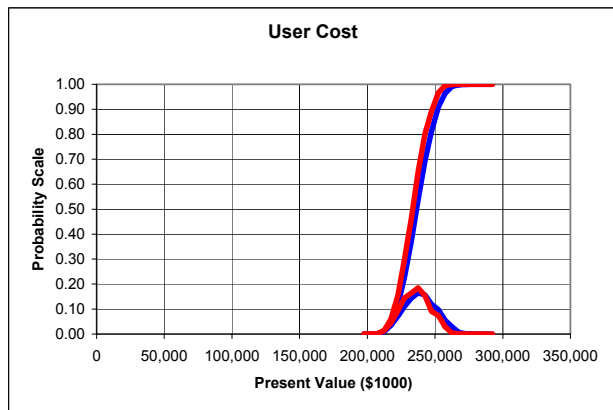

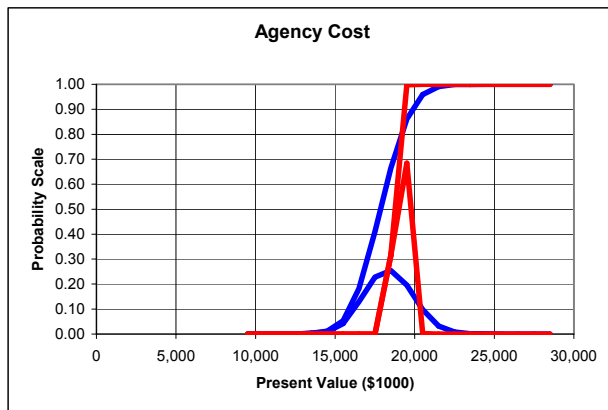

Based on the deterministic analysis, the PCC alternative is slightly higher for the present value of agency costs (approximately 1.3 percent higher) than the HMA alternative. For the present value of user costs, the PCC alternative is slightly lower (approximately 1.00 percent lower) than the HMA alternative. Based on total present value costs, these two alternatives would be considered equivalent (PCC is approximately 0.8 percent lower than HMA).

## Probabilistic Results

Total Cost (Present Value)	Alternative 1: HMA		Alternative 2: PCC	
	Agency Cost (\$1000)	User Cost (\$1000)	Agency Cost (\$1000)	User Cost (\$1000)
Mean	\$18,365.23	\$239,105.37	\$19,153.28	\$236,004.03
Standard Deviation	\$1,511.70	\$11,478.88	\$271.21	\$10,363.83
Minimum	\$13,083.68	\$209,885.91	\$18,553.22	\$209,779.17
Maximum	\$24,641.06	\$275,664.34	\$20,249.69	\$265,385.41

Total Cost (Present Value)	Alternative 1: HMA		Alternative 2: PCC	
	Agency Cost (\$1000)	User Cost (\$1000)	Agency Cost (\$1000)	User Cost (\$1000)
Mean	\$18,365.23	\$239,105.37	\$19,153.28	\$236,004.03
Standard Deviation	\$1,511.70	\$11,478.88	\$271.21	\$10,363.83
Minimum	\$13,083.68	\$209,885.91	\$18,553.22	\$209,779.17
Maximum	\$24,641.06	\$275,664.34	\$20,249.69	\$265,385.41

Based on the cumulative risk profile shown above, there is a 90 percent probability that the agency costs for the PCC alternative will be less than the HMA alternative. The slopes of the cumulative risk profiles shown above are quite similar for the user costs and only a slight difference for the agency costs. The alternative with the steeper slope would have less variability and therefore would be the preferred alternative.

## **APPENDIX 3 – POSSIBLE ENGINEERING ANALYSIS ITEMS FOR CONSIDERATION**

- Air pollution impacts. Consider if either effects on traffic or effects during production affect the project or future preservation efforts
- Non-user impacts. How are surrounding neighborhoods affected by the project? How do these impacts vary depending on the type of pavement selected? What are the impacts at the point of production?
- Haul routes through neighborhoods. Consider the impacts both during initial construction and future preservation projects.
- Future ability of plants to operate at night in urban areas and associated cost increases. Where are typical production plants located? Will night work continue to be feasible in the area of plant production or will urban growth affect this? What possible effect will urban growth have on making production plants move further away from the corridor?
- Neighborhood impacts due to trip diversion during preservation projects. When a highway closure impacts the traveling public, many will divert to other routes to avoid delays. These diversions have associated costs, in and of themselves. Some of the costs come from backups and delays (user impacts) on these diversion routes; some of the costs come from impacts to neighborhoods, through increased traffic, noise, congestion, air pollution, safety and accident risks. Consider the level of user delays and the likelihood that diversions will occur and the level of impact these diversions could have on non-highway users.
- Business impacts due to reduced or restricted access. This impact happens both due to direct impacts to users and to impacts due to diversion. The magnitude grows as an area urbanizes and increases the number of businesses that stay open for extended (mostly nighttime) hours of operation. Diversion through a neighborhood with extensive commercial business can greatly impact those businesses.
- Effect of nighttime noise variances and risk of approval of noise variances. These two items tie in with the item noted above. As urban areas grow, nighttime noise variances become more difficult to obtain and more restrictive in their limitations. Review the corridor in question and the expected growth projections, to develop an idea of the risk associated with this non-user impact. Noise restrictions can limit hours of operations to the point of preventing work, or they can restrict noise levels below that achievable by state of the practice construction equipment. Noise restrictions apply also to vibration and noise generated by vibratory equipment and these restrictions can prevent the use of particular equipment within selected urban corridors. A single resident affected by nighttime noise can and has effectively shut down projects, forcing a move to day work and created huge impacts on highway users through delay and impacts.
- Noise
  - Pavement noise. Pavement surface texture can have an effect on noise through a corridor with some pavement surfaces being measurably quieter than others
  - Noise walls. Evaluate whether the corridor already has noise walls or is expected to have noise walls by the time of the project, and the impacts having or not having the walls might have on non-users/residents, both for construction noise and pavement noise
  - Haul through neighborhoods, at night. Haul through neighborhoods at night (and if you are hauling, you are traveling through *someone's* neighborhood) should be considered as an impact. Sparsely populated areas will obviously have a smaller impact due to the noise of hauling vehicles than will densely packed urban areas.
  - Noise from diverted traffic and other impacts. Diverted traffic must drive through someone's neighborhood to get to where they are going. At night, diverted traffic, especially involving large trucks, can have a significant noise impact on neighborhoods.
  - Noise generation during preservation projects. When preservation projects are performed on any pavement, noise is generated and its impacts on the local community must also be considered, in addition to the impact of the noise from the initial construction.
- Safety.
  - Public exposure to traffic control during lane closures.
  - Work exposure to traffic during lane closures.

- Lane closures are a safety risk factor for both workers and the traveling public. Limited vision, nighttime lighting, temporary traffic control and other factors increase the risk of accidents to both motorists and to workers within the work zone. Evaluate the risk to both, given the nature of the corridor, the ADT, the degree of urbanization and the complexity of the facility.
  - Safety risks associated with maintenance by state forces between preservation projects.
- Pavement type continuity within a corridor (similar to architectural choices for structures and wall-types within a corridor and landscape architectural choices for continuity within a corridor). It is generally not desirable to switch pavement types over relatively short stretches of highway. Maintenance needs change for each given pavement type, as do preservation needs. Further, the change in pavement type impacts the public in various ways, including aesthetics.
- Environmental effects.
  - Runoff temperature due to heating effects depending on pavement type. Evaluate in conjunction with design of the storm sewer system.

## **APPENDIX 4 – DOWEL BAR TYPE SELECTION PROTOCOL**

Dowel bars in Portland Cement Concrete (PCC) pavement have been proven to extend pavement life. Dowel bars transfer loads from panel to panel, supplementing the aggregate interlock at the panel joint. Aggregate interlock at the joint degrades over time, while dowel bars are expected to continue to be effective at load transfer for upwards of 50 years. WSDOT PCC pavements are designed to last 50 years, so it is critical that the dowel bars also survive, intact and functional, for this period.

Different materials used for dowel bars have different expected performance lives, given various exposures to weather and corrosive chemicals. Dowel bars in wet environments with exposure to salts/corrosive agents (either naturally from the environment, such as sea spray, or from chemical anti-icing compounds) are the harshest environments. Dowel bars placed in dry climates without exposure to salts/corrosive agents experience the mildest environment. For the same moisture and salt/corrosive environment, warmer climates would induce more corrosion than colder environments.

The purpose of this protocol is to balance risk and cost. In an unconstrained funding scenario, one would select the least risky dowel bar material: one most resistant to corrosion. Unfortunately, WSDOT will always be under some type of funding constraint. Risk and cost, for each type of dowel bar material, is illustrated in the following table:

<b>Dowel Bar Type</b>	<b>Cost</b>	<b>Corrosion Resistance</b>
Solid stainless steel	Most expensive	Best corrosion resistance
Stainless steel clad	↓	↓
Stainless steel sleeve with epoxy coated insert	↓	↓
MMFX2 steel (patented steel using chromium below limits to qualify as stainless and microstructure to resist corrosion)	↓	↓
Epoxy coated	↓	↓
Black steel (uncoated)	Least expensive	Worst corrosion resistance

Corrosion resistance increases as does cost when moving from black steel to stainless steel dowels. Additionally, there is a direct link, then, between risk and cost: less risk, higher cost; lowest cost, greatest risk of corrosion before 50 years.

#### **CLIMATE REGIMES**

Wet climates promote corrosion in steel more than drier climates. In general, western Washington has the greatest exposure to moisture in PCC pavements. Most of eastern Washington is considerably drier, experiencing more snow but less rainfall, and less overall moisture, than western Washington.

#### **CORROSION REGIMES**

PCC pavement directly adjacent to salt water has a high-risk exposure to corrosive salts. Fortunately, little PCC pavement has this type of exposure in Washington State. The greatest exposure to corrosive salts will be in locations where the highway is regularly treated with salts/corrosive agents during the winter months. Mountain passes, particularly those with “clear

pavement” protocols (wherein Maintenance maintains the highway in a snow/ice free condition) will have the greatest exposure.

## **TRAFFIC LOADING**

Trucks present the greatest loading risk for load transfer between adjacent PCC pavement panels. Truck lanes (usually Lane 1 or Lane 2, depending on the total number of lanes and following WSDOT lane counting protocol which starts from the slow lane as lane 1 and works toward the fast lane) will have the greatest number of ESALs (Equivalent Single Axle Load, a measure of the traffic loading experienced by a pavement). Risk of load transfer failure increases with increasing ESALs. Lanes with the greatest truck traffic will need more dowels to ensure efficient load transfer. On multi-lane highways, the “auto” lanes (Lanes 3, 4 or 5) will typically have much fewer trucks. These lanes can probably be designed with fewer dowel bars per lane and still reach a 50-year pavement life.

## **TYPES OF DOWEL BAR ALTERNATES**

### **1. Stainless steel clad alternates**

- Stainless steel clad. These bars employ a patented manufacturing process that metallurgically bonds ordinary steel and stainless steel. The bars have a black steel interior surrounded by a stainless steel cladding. Currently manufactured by Stelax (UK).
- Stainless steel sleeves with an epoxy coated dowel bar insert. These bars have an epoxy-coated bar that is inserted into a thin walled stainless steel tube. Currently manufacturer by CMI (USA).

### **2. Non-stainless, corrosion resistant alternates**

- MMFX2 steel dowel bars. These bars are high chromium but below the threshold to be classified as stainless. In addition, these bars have a dual phase steel microstructure that resists corrosion. Currently patented and manufactured by MMFX Steel Corporation (USA).

### **3. Epoxy coated**

- Epoxy coated. Traditional black steel bars with epoxy coating

Note: solid stainless bars are not recommended at this time due to their high initial cost. Other non-stainless, corrosion resistant bar alternatives are under investigation but are not yet approved for use. (These would include heavy galvanized steel bars and dual-phase steel bars).

## **APPLICATION OF DOWEL BAR TYPE SELECTION**

### **1. Western Washington**

Preferred Dowel Bar Type: **Stainless steel clad alternates**

Preferred Dowel Bar Spacing:

- Truck Lanes (lanes 1 and 2 in multi-lane highways): Twelve dowel bars per joint
- Non-truck lanes (Lanes 3, 4 or 5 in multi-lane highways): Eight dowel bars per joint (Four in each wheel path)
- HOV lanes: Eight dowel bars per joint (Four in each wheel path)

Note: the design for HOV lanes assumes these will remain as HOV lanes. The designer/engineer of record should carefully examine the potential future use of the HOV lanes to estimate the risk of this lane being converted to use by truck traffic. If there is a significant risk of the HOV lane being converted to a truck traffic lane, then a twelve dowel bars per joint configuration should be used.

### **2. Mountain Passes (greater than 2000 foot elevation)**

Preferred Dowel Bar Type: **Stainless steel clad alternates**

Preferred Dowel Bar Spacing:

- Truck Lanes (lanes 1 and 2 in multi-lane highways, and in lanes 1 and 2 in two lane sections): Twelve dowel bars per joint
- Non-truck lanes (Lanes 3, 4 or 5 in multi-lane highways): Eight dowel bars per joint (Four in each wheel path)

### 3. Eastern Washington

Preferred Dowel Bar Type: **Non-stainless, corrosion resistant alternates (MMFX2)**

Preferred Dowel Bar Spacing:

- Truck Lanes (lanes 1 and 2 in multi-lane highways): Twelve dowel bars per joint
- Non-truck lanes (Lanes 3, 4, or 5 in multi-lane highways): Eight dowel bars per joint (Four in each wheel path)

### 4. Concrete shoulders

The designer / engineer of record should carefully examine the potential future use of concrete shoulders built adjacent to mainline PCC. Dowel bars may be omitted from the left shoulder if the shoulder is never expected to carry a full traffic load and is only to experience breakdown traffic. For the right shoulder, two options are applicable: 1) construct a 14 foot wide doweled right lane, stripe at 12 feet, and only tie the concrete shoulder, or 2) construct a 12 foot wide doweled right lane with a tied and doweled concrete shoulder. Any shoulder that has a potential for being used as traveled way (shifting traffic lanes onto the shoulders to gain an extra lane, for example) should be evaluated for dowel bars placement. If the shoulder requires dowel bars based on the above review, then dowel bars placement and type must match the adjacent mainline selection.

### 5. Dowel Bar Retrofit (DBR) projects

Preferred Dowel Bar Type: Epoxy coated or non-stainless, corrosion resistant alternates. DBR projects are projected to have useful lives of about 15 years, reducing the need for highly corrosion resistant dowel bars. Epoxy coated bars have typically been used in DBR, but non-stainless, corrosion resistant bars could be allowed as an alternate. Dowel bar spacing remains three bars per wheel path.

## **APPENDIX 5 – WSDOT PAVEMENT TYPE SELECTION COMMITTEE CORRESPONDENCES**

June 29, 2004

TO: Don Nelson, 47321

FROM: Tom Baker, 47365

SUBJECT: Pavement Type Selection Protocol

When the pavement type selection has been completed and forwarded to the State Materials Laboratory, the Pavement Division will formulate the Pavement Type Selection Committee (referred to as the Committee) Approval Letter and request that each member of the Committee sign and forward the letter on to the next member. The Committee is not required to convene if the life cycle cost analysis between the alternatives is greater than 15 percent and the recommendations are acceptable to both the Region and the State Materials Laboratory. The Approval Letter shall provide the necessary documentation that supports the Committee's selection of the pavement type.

Projects to be reviewed shall be distributed to the Committee members for approval (see attached example of Approval Letter). Based on this review and obtaining consensus from the Committee, the Pavement Division will either process the Approval Letter, take appropriate action to obtain consensus, or convene the Committee.

In order to expedite the required time and expended level of effort for the review of pavement type selection projects, the following procedure is recommended:

1. The Committee should convene if the pavement type recommended by the Region is contrary to pavement design and engineering analysis recommendations. The pavement design and engineering analysis recommendations shall be subject to the review of the Pavement Division or any member of the Committee. Under these circumstances it shall be the responsibility of the Pavements Division or the Committee member to formulate, in writing, why the selected pavement type is not appropriate and distribute his/her rationale to all members. If all members agree with the recommendations a meeting will not be necessary, otherwise, the Committee should convene.
2. The Committee should convene at the request of any member.

TEB:imp

## PAVEMENT TYPE SELECTION

SR-3  
Luoto Road to SR-305  
MP 48.90 to MP 53.00

The Pavement Type Selection Committee has completed its review of the pavement type selection for the project SR-3 Luoto Road to SR-305, MP 48.90 to MP 53.00.

The project consists of constructing the final two lanes of the ultimate four-lane facility from Luoto Road to SR-305.

The pavement design analysis resulted in both pavement types (HMA and PCC) being viable. In the life cycle cost analysis, one PCC alternative was compared to one HMA alternative. In the life cycle cost analysis of the two alternatives, there is a cost advantage in the use of HMA over PCC of greater than 15 percent. The Committee approves the use of HMA on this project.
